# Code Generation for Control Flow Constructs

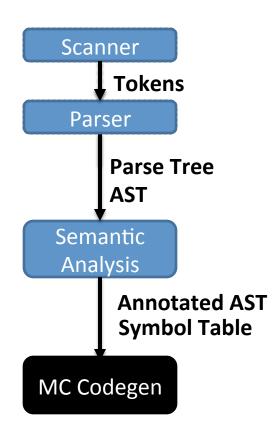

# Roadmap

#### Last time:

- Got the basics of MIPS
- CodeGen for some AST node types

#### This time:

- Do the rest of the AST nodes
- Introduce control flow graphs

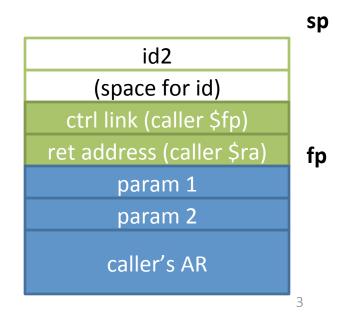

# A Quick Warm-Up: MIPS for id = 1 + 2;

```
li
                $t0 1
                $t0 0($sp)
  push 1
          SW
                $sp $sp 4
          subu
                $t0 2
          li
  push 2
                $t0 0($sp)
          SW
          subu $sp $sp 4
                $t1 4($sp)
          lw
pop opR
          addu $sp $sp 4
                $t0 4($sp)
          lw
pop opL
          addu $sp $sp 4
                $t0 $t0 $t1
 Do 1+2
          add
                    0($sp)
                $t0
          SW
push RHS-
          subu $sp $sp 4
                $t0 - 8($fp)
          la
push LHS
                $t0 0($sp)
          SW
          subu $sp $sp 4
                $t1 4($sp)
          lw
pop LHS
                $sp $sp 4
          addu
                $t0
          lw
                    4 ($sp)
pop RHS
                $sp $sp 4
          addu
                $t0
                    0 ($t1)
          SW
Do assign
```

#### **General-Purpose Algorithm**

- 1) Compute RHS expr on stack
- 2) Compute LHS *location* on stack
- 3) Pop LHS into \$t1
- 4) Pop RHS into \$t0
- 5) Store value \$t0 at address \$t1

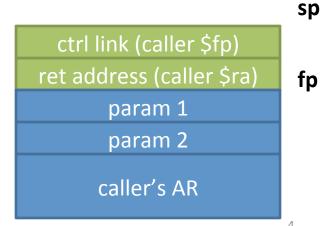

# Same Example if id was Global

```
li
                $t0 1
                $t0 0($sp)
  push 1
          SW
                $sp $sp 4
          subu
                $t0 2
          li
  push 2
                $t0 0($sp)
          SW
          subu $sp $sp 4
                $t1 4($sp)
          lw
pop opR
          addu $sp $sp 4
                $t0 4($sp)
          lw
pop opL
          addu $sp $sp 4
                $t0 $t0 $t1
 Do 1+2
          add
                    0($sp)
                $t0
          SW
push RHS-
          subu $sp $sp 4
                $t0 = $($ip) id
          la
push LHS
                $t0 0($sp)
          SW
          subu $sp $sp 4
                $t1 4($sp)
          lw
pop LHS
                $sp $sp 4
          addu
                $t0
                    4($sp)
          lw
pop RHS
                $sp $sp 4
          addu
                $t0
                    0 ($t1)
          SW
Do assign
```

#### **General-Purpose Algorithm**

- 1) Compute RHS expr on stack
- Compute LHS *location* on stack
- Pop LHS into \$t1
- Pop RHS into \$t0
- 5) Store value \$t0 at address \$t1

# Do We *Need* LHS computation ?

This is a bit much when the LHS is a variable

- We end up doing a single load to find the address, then a store, then a load
- We know a lot of the computation at compile time

# Static v Dynamic Computation

#### Static

Perform the computation at compile-time

#### Dynamic

Perform the computation at runtime

#### As applied to memory addresses...

- Global variable location
- Local variable
- Field offset

# More Complex LHS addresses

```
Chain of dereferences
    java: a.b.c.d
Array cell address
    arr[1]
    arr[c]
    arr[1][c]
    arr[c][1]
```

# Dereference Computation

```
struct LinkedList{
                                                0x1002F000
                                                                   num: 3
   int num;
                                                                  next: 0x0
   struct LinkedList& next;
                                               list.next.next
                                                                   num: 2
                                                 0x10040000
list.next.next.num = list.next.num
                                                              next: 0x1002F000
    multi-step code to
                            multi-step code to
                                                  list.next
    load this address
                             load this value
                                                          list
```

- Get base addr of list
- Get offset to next field
- Load value in next field
- Get offset to next field
- Load value in next field
- Get offset to num field
- Load that address

next: 0x10040000

### Control Flow Constructs

**Function Calls** 

Loops

Ifs

#### **Function Call**

#### Two tasks:

- Put argument values on the stack (pass-by-value semantics)
- Jump to the callee preamble label
- Bonus 3<sup>rd</sup> task: save *live* registers
  - (We don't have any in a stack machine)
- Semi-bonus 4<sup>th</sup> task: retrieve result value

# Function Call Example

```
int f(int arg1, int arg2) {
  return 2;
int main(){
  int a;
 a = f(a, 4);
li $t0 4
                # push arg 2
sw $t0 0($sp)
subu $sp $sp 4
lw $t0 -8 ($fp)
                # push arg 1
sw $t0 0($sp)
subu $sp $sp 4
jal f
                # goto f
addu $sp $sp 8 # tear down params
sw $v0 - 8($fp) # retrieve result
```

### We Need a New Tool

#### Control Flow Graph

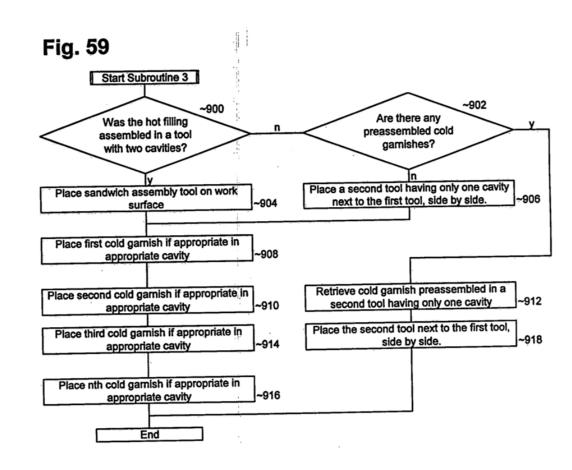

- Important representation for program optimization
- Helpful way to visualize source code

# Control Flow Graphs: the Other CFG

# Think of a CFG like a flowchart

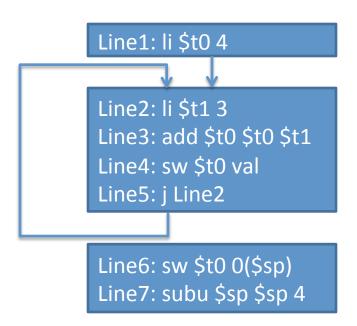

- Each block is a set of instructions
- Execute the block, decide on next block

#### **Basic Blocks**

Nodes in the CFG
Largest run of instructions
that will always be
executed in sequence

```
Line1: li $t0 4
Line2: li $t1 3
Line3: add $t0 $t0 $t1
Line4: sw $t0 val
Line5: j Line2
Line6: sw $t0 0($sp)
Line7: subu $sp $sp 4
```

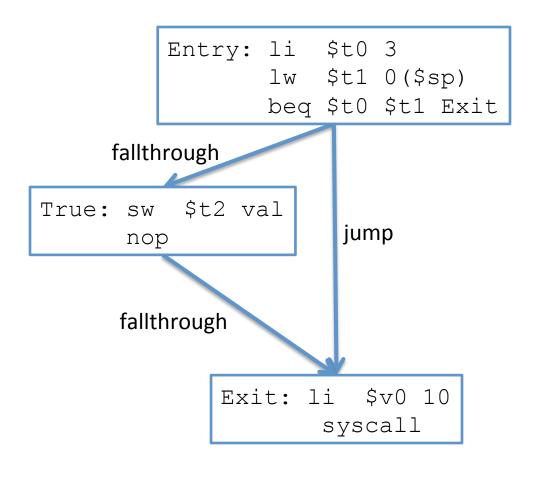

### **Conditional Blocks**

Branch instructions cause a node to have multiple out-edges

```
Entry: li $t0 3
    lw $t1 0($sp)
    beq $t0 $t1 Exit
True: sw $t2 val
    nop
Exit: li $v0 10
```

syscall

# Generating If-then Stmts

First, get label for the exit

Generate the head of the if

Make jumps to the (not-yet placed!) exit label

Generate the true branch

Write the body of the true node

Place the exit label

### If-then Stmts

```
sw $t0 0($sp) # push onto stack
if (val == 1) {
                   subu $sp $sp 4
  val = 2;
                   sw $t0 0($sp) # push onto stack
                   subu $sp $sp 4
                   addu $sp $sp 4
                   lw $t0 4($sp)
                   addu $sp $sp 4
                   li $t0 2
                   sw $t0 val
```

nop

L 0:

```
lw $t0 val  # evaluate condition LHS
li $t0 1  # evaluate condition RHS
lw $t1 4 ($sp)  # pop RHS into $t1
                # pop LHS into $t0
bne $t0 $t1 L 0 # skip if condition false
                # Loop true branch
                # end true branch
                # branch successor
```

### **Conditional Blocks**

```
Entry: li $t0 3
       lw $t1 0($sp)
       beg $t0 $t1 False
 True: sw $t2 val
       j Exit
                              Entry: li $t0 3
False: sw $t2 val2
                                     lw $t1 0($sp)
       nop
                                     beq $t0 $t1 False
 Exit: li $v0 10
                          fallthrough
       syscall
                                                      jump
                     True: sw $t2 val
                                               False: sw $t2 val
                           j Exit
                                                      nop
                              jump
                                                     fallthrough
                                  Exit: li
                                             $v0 10
                                          syscall
```

### Generating If-then-Else Stmts

First, get name for the false and exit labels Generate the head of the if

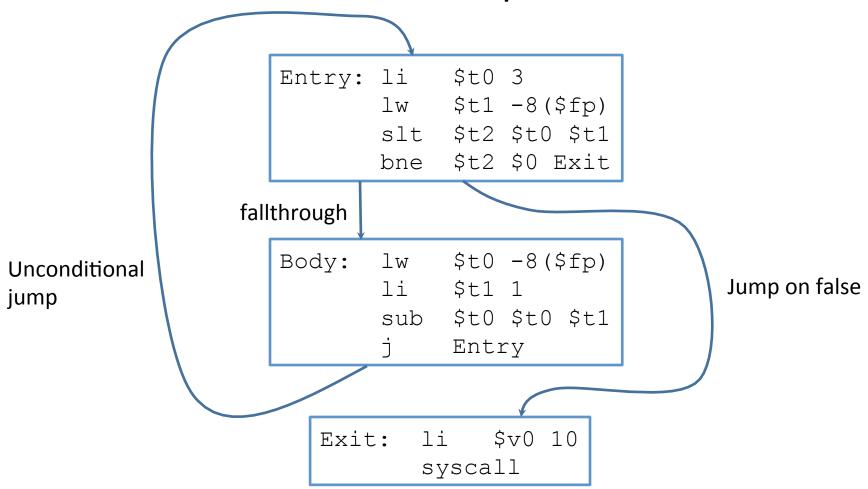

- Make jumps to the (not-yet placed!) exit and false labels
- Generate the true branch
- Write the body of the true node
- Jump to the (not-yet placed!) exit label
- Generate the false branch
- Place the false label
- Write the body of the false node

Place the exit label

### If-then-Else Stmts

```
lw $t0 val  # evaluate condition LHS
                   sw $t0 0($sp) # push onto stack
if (val == 1) {
                   subu $sp $sp 4
  val = 2;
                   li $t0 1  # evaluate condition RHS
} else {
                   sw $t0 0($sp) # push onto stack
  val = 3;
                   subu $sp $sp 4 #
                   lw $t1 4($sp)  # pop RHS into $t1
                   addu $sp $sp 4
                   lw $t0 4($sp)
                                   # pop LHS into $t0
                   addu $sp $sp 4
                   bne $t0 $t1 L 1 # branch if condition
                                     false
                   li $t0 2
                                   # Loop true branch
                   sw $t0 val
                                   # end true branch
                   j L O
                                   # false branch
                 L 1:
                 L 0:
                                   # branch successor
                                                        20
```

# While Loops CFG

# Generating While Loops

#### Very similar to if-then stmts

- Generate a bunch of labels
- Label for the head of the loop
- Label for the successor of the loop

At the end of the loop body

Unconditionally jump back to the head

# While Loop

```
L 0:
                   sw $t0 0($sp) # push onto stack
                   subu $sp $sp 4
                   li $t0 1
                                  # evaluate condition RHS
                   sw $t0 0($sp)
                                  # push onto stack
while (val == 1) {
                                  #
                   subu $sp $sp 4
  val = 2;
                   lw $t1 4($sp)
                                  # pop RHS into $t1
                                  #
                   addu $sp $sp 4
                   lw $t0 4($sp)
                                  # pop LHS into $t0
                                  #
                   addu $sp $sp 4
                   bne $t0 $t1 L 1
                                  # branch loop end
                   li $t0 2
                                  # Loop body
                   sw $t0 val
                   j L O
                                  # jump to loop head
                  L 1:
                                  # Loop successor
```

#### A Note on Conditionals

We lack instructions for branching on most relations

- No "branch if reg1 < reg2"</p>
- Instead we use the slt "set less than"
  - slt \$t2 \$t1 \$t0
    - \$t2 is 1 when \$t1 < \$t0
    - \$t2 otherwise set to 0

# P6 Helper Functions

```
Generate (opcode, ...args...)
```

- Generate("add", "T0", "T0", "T1")
  - writes out add \$t0, \$t0, \$t1
- Versions for fewer args as well

Generate indexed (opcode, "Reg1", "Reg2", offset)

GenPush(reg) / GenPop(reg)

NextLabel() – Gets you a unique label

GenLabel(L) -Places a label

### Questions?

#### Looking forward

- More uses of the CFG
- Program analysis
- Optimization

Homework: see QtSpim resources

# QtSpim
